(57) **ABSTRACT**

A novel canola variety designated 45S52 and seed, plants and plant parts thereof, produced by crossing Pioneer Hi-Bred International, Inc. proprietary inbred canola varieties. Methods for producing a canola plant that comprises crossing canola variety 45S52 with another canola plant. Methods for producing a canola plant containing in its genetic material one or more traits introgressed into 45S52 through backcross conversion and/or transformation, and to the canola seed, plant and plant part produced thereby. This invention relates to the canola variety 45S52, the seed, the plant produced from the seed, and variants, mutants, and minor modifications of canola variety 45S52. This invention further relates to methods for producing canola varieties derived from canola variety 45S52.

**CANOLA HYBRID 45S52****CROSS REFERENCE TO RELATED APPLICATIONS**

This application is a continuation of application Ser. No. 13/080,022 filed Apr. 5, 2011, the disclosure of which is incorporated herein by reference.

**FIELD OF THE INVENTION**

The invention is in the field of *Brassica napus* breeding (i.e., canola breeding), specifically relating to the canola hybrid designated 45S52.

**BACKGROUND OF THE INVENTION**

The present invention relates to a novel rapeseed variety designated 45S52 which is the result of years of careful breeding and selection. Since such variety is of high quality and possesses a relatively low level of erucic acid in the vegetable oil component and a relatively low level of glucosinolate content in the meal component, it can be termed "canola" in accordance with the terminology commonly used by plant scientists.

The goal of plant breeding is to combine in a single variety or hybrid various desirable traits. For field crops, these traits may include resistance to diseases and insects, tolerance to heat and drought, reducing the time to crop maturity, greater yield, and better agronomic quality. With mechanical harvesting of many crops, uniformity of plant characteristics such as germination and stand establishment, growth rate, maturity, and plant and pod height, is important. The creation of new superior, agronomically sound, and stable high-yielding cultivars of many plant types including canola has posed an ongoing challenge to plant breeders. Therefore, there is a continuing need in the field of agriculture for canola plants having desirable agronomic and industrial characteristics.

**SUMMARY OF THE INVENTION**

According to the present invention, there is provided a novel *Brassica napus* hybrid designated 45S52. This invention thus relates to the seeds of the 45S52 hybrid, to plants of the 45S52 hybrid, and to methods for producing a canola plant by crossing the 45S52 hybrid with itself or another canola plant (whether by use of male sterility or open pollination), and to methods for producing a canola plant containing in its genetic material one or more transgenes, and to transgenic plants produced by that method. This invention also relates to canola seeds and plants produced by crossing the hybrid 45S52 with another line.

**DETAILED DESCRIPTION OF THE INVENTION**

Field crops are bred through techniques that take advantage of the plant's method of pollination. A plant is self-pollinated if pollen from one flower is transferred to the same or another flower of the same plant or a genetically identical plant. A plant is sib-pollinated when individuals within the same family or line are used for pollination. A plant is cross-pollinated if the pollen comes from a flower on a genetically different plant from a different family or line. The term "cross-pollination" used herein does not include self-pollination or sib-pollination.

In the practical application of a chosen breeding program, the breeder often initially selects and crosses two or more

2

parental lines, followed by repeated selfing and selection, thereby producing many unique genetic combinations. The breeder can theoretically generate billions of different genetic combinations via crossing, selfing and mutagenesis. However, the breeder commonly has no direct control at the cellular level of the plant. Therefore, two breeders will never independently develop the same variety having the same canola traits.

In each cycle of evaluation, the plant breeder selects the germplasm to advance to the next generation. This germplasm is grown under chosen geographical, climatic and soil conditions, and further selections are then made during and at the end of the growing season. The characteristics of the varieties developed are incapable of prediction in advance. This unpredictability is because the selection occurs in unique environments, with no control at the DNA level (using conventional breeding procedures), and with millions of different possible genetic combinations being generated. A breeder of ordinary skill cannot predict in advance the final resulting varieties that are to be developed, except possibly in a very gross and general fashion. Even the same breeder is incapable of producing the same variety twice by using the same original parents and the same selection techniques. This unpredictability commonly results in the expenditure of large research monies and effort to develop a new and superior canola variety.

Canola breeding programs utilize techniques such as mass and recurrent selection, backcrossing, pedigree breeding and haploidy. For a general description of rapeseed and Canola breeding, see, Downey and Rakow, (1987) "Rapeseed and Mustard" In: *Principles of Cultivar Development*, Fehr, (ed.), pp 437-486; New York; Macmillan and Co.; Thompson, (1983) "Breeding winter oilseed rape *Brassica napus*"; *Advances in Applied Biology* 7:1-104; and Ward, et. al., (1985) *Oilseed Rape*, Farming Press Ltd., Wharfedale Road, Ipswich, Suffolk, each of which is hereby incorporated by reference.

Recurrent selection is used to improve populations of either self- or cross-pollinating *Brassica*. Through recurrent selection, a genetically variable population of heterozygous individuals is created by intercrossing several different parents. The best plants are selected based on individual superiority, outstanding progeny, and/or excellent combining ability. The selected plants are intercrossed to produce a new population in which further cycles of selection are continued. Various recurrent selection techniques are used to improve quantitatively inherited traits controlled by numerous genes.

Breeding programs use backcross breeding to transfer genes for a simply inherited, highly heritable trait into another line that serves as the recurrent parent. The source of the trait to be transferred is called the donor parent. After the initial cross, individual plants possessing the desired trait of the donor parent are selected and are crossed (backcrossed) to the recurrent parent for several generations. The resulting plant is expected to have the attributes of the recurrent parent and the desirable trait transferred from the donor parent. This approach has been used for breeding disease resistant phenotypes of many plant species, and has been used to transfer low erucic acid and low glucosinolate content into lines and breeding populations of *Brassica*.

Pedigree breeding and recurrent selection breeding methods are used to develop varieties from breeding populations. Pedigree breeding starts with the crossing of two genotypes, each of which may have one or more desirable characteristics that is lacking in the other or which complements the other. If the two original parents do not provide all of the desired characteristics, other sources can be included in the breeding

population. In the pedigree method, superior plants are selfed and selected in successive generations. In the succeeding generations the heterozygous condition gives way to homozygous lines as a result of self-pollination and selection. Typically in the pedigree method of breeding, five or more generations of selfing and selection are practiced:  $F_1$  to  $F_2$ ;  $F_2$  to  $F_3$ ;  $F_3$  to  $F_4$ ;  $F_4$  to  $F_5$ , etc. For example, two parents that are believed to possess favorable complementary traits are crossed to produce an  $F_1$ . An  $F_2$  population is produced by selfing one or several  $F_1$ 's or by intercrossing two  $F_1$ 's (i.e., sib mating). Selection of the best individuals may begin in the  $F_2$  population, and beginning in the  $F_3$  the best individuals in the best families are selected. Replicated testing of families can begin in the  $F_4$  generation to improve the effectiveness of selection for traits with low heritability. At an advanced stage of inbreeding (i.e.,  $F_6$  and  $F_7$ ), the best lines or mixtures of phenotypically similar lines commonly are tested for potential release as new cultivars. Backcrossing may be used in conjunction with pedigree breeding; for example, a combination of backcrossing and pedigree breeding with recurrent selection has been used to incorporate blackleg resistance into certain cultivars of *Brassica napus*.

Plants that have been self-pollinated and selected for type for many generations become homozygous at almost all gene loci and produce a uniform population of true breeding progeny. If desired, double-haploid methods can also be used to extract homogeneous lines. A cross between two different homozygous lines produces a uniform population of hybrid plants that may be heterozygous for many gene loci. A cross of two plants each heterozygous at a number of gene loci will produce a population of hybrid plants that differ genetically and will not be uniform.

The choice of breeding or selection methods depends on the mode of plant reproduction, the heritability of the trait(s) being improved, and the type of cultivar used commercially, such as  $F_1$  hybrid variety or open pollinated variety. A true breeding homozygous line can also be used as a parental line (inbred line) in a commercial hybrid. If the line is being developed as an inbred for use in a hybrid, an appropriate pollination control system should be incorporated in the line. Suitability of an inbred line in a hybrid combination will depend upon the combining ability (general combining ability or specific combining ability) of the inbred.

Various breeding procedures are also utilized with these breeding and selection methods. The single-seed descent procedure in the strict sense refers to planting a segregating population, harvesting a sample of one seed per plant, and using the one-seed sample to plant the next generation. When the population has been advanced from the  $F_2$  to the desired level of inbreeding, the plants from which lines are derived will each trace to different  $F_2$  individuals. The number of plants in a population declines each generation due to failure of some seeds to germinate or some plants to produce at least one seed. As a result, not all of the  $F_2$  plants originally sampled in the population will be represented by a progeny when generation advance is completed.

In a multiple-seed procedure, canola breeders commonly harvest one or more pods from each plant in a population and thresh them together to form a bulk. Part of the bulk is used to plant the next generation and part is put in reserve. The procedure has been referred to as modified single-seed descent or the pod-bulk technique. The multiple-seed procedure has been used to save labor at harvest. It is considerably faster to thresh pods with a machine than to remove one seed from each by hand for the single-seed procedure. The multiple-seed procedure also makes it possible to plant the same number of seeds of a population each generation of inbreed-

ing. Enough seeds are harvested to make up for those plants that did not germinate or produce seed. If desired, doubled-haploid methods can be used to extract homogeneous lines.

Molecular markers, including techniques such as Isozyme Electrophoresis, Restriction Fragment Length Polymorphisms (RFLPs), Randomly Amplified Polymorphic DNAs (RAPDs), Arbitrarily Primed Polymerase Chain Reaction (AP-PCR), DNA Amplification Fingerprinting (DAF), Sequence Characterized Amplified Regions (SCARs), Amplified Fragment Length Polymorphisms (AFLPs), Simple Sequence Repeats (SSRs) and Single Nucleotide Polymorphisms (SNPs), may be used in plant breeding methods. One use of molecular markers is Quantitative Trait Loci (QTL) mapping. QTL mapping is the use of markers which are known to be closely linked to alleles that have measurable effects on a quantitative trait. Selection in the breeding process is based upon the accumulation of markers linked to the positive effecting alleles and/or the elimination of the markers linked to the negative effecting alleles in the plant's genome.

Molecular markers can also be used during the breeding process for the selection of qualitative traits. For example, markers closely linked to alleles or markers containing sequences within the actual alleles of interest can be used to select plants that contain the alleles of interest during a backcrossing breeding program. The markers can also be used to select for the genome of the recurrent parent and against the markers of the donor parent. Using this procedure can minimize the amount of genome from the donor parent that remains in the selected plants. It can also be used to reduce the number of crosses back to the recurrent parent needed in a backcrossing program. The use of molecular markers in the selection process is often called Genetic Marker Enhanced Selection or Marker Assisted Selection (MAS).

The production of doubled haploids can also be used for the development of inbreds in the breeding program. In *Brassica napus*, microspore culture technique is used in producing haploid embryos. The haploid embryos are then regenerated on appropriate media as haploid plantlets, doubling chromosomes of which results in doubled haploid plants. This can be advantageous because the process omits the generations of selfing needed to obtain a homozygous plant from a heterozygous source.

A pollination control system and effective transfer of pollen from one parent to the other offers improved plant breeding and an effective method for producing hybrid canola seed and plants. For example, the ogura cytoplasmic male sterility (cms) system, developed via protoplast fusion between radish (*Raphanus sativus*) and rapeseed (*Brassica napus*), is one of the most frequently used methods of hybrid production. It provides stable expression of the male sterility trait (Ogura, 1968, Pelletier, et al., 1983) and an effective nuclear restorer gene (Heyn, 1976).

In developing improved new *Brassica* hybrid varieties, breeders may use self-incompatible (SI), cytoplasmic male sterile (CMS) or nuclear male sterile (NMS) *Brassica* plants as the female parent. In using these plants, breeders are attempting to improve the efficiency of seed production and the quality of the  $F_1$  hybrids and to reduce the breeding costs. When hybridization is conducted without using SI, CMS or NMS plants, it is more difficult to obtain and isolate the desired traits in the progeny ( $F_1$  generation) because the parents are capable of undergoing both cross-pollination and self-pollination. If one of the parents is a SI, CMS or NMS plant that is incapable of producing pollen, only cross pollination will occur. By eliminating the pollen of one parental variety in a cross, a plant breeder is assured of obtaining

hybrid seed of uniform quality, provided that the parents are of uniform quality and the breeder conducts a single cross.

In one instance, production of  $F_1$  hybrids includes crossing a CMS *Brassica* female parent with a pollen-producing male *Brassica* parent. To reproduce effectively, however, the male parent of the  $F_1$  hybrid must have a fertility restorer gene (Rf gene). The presence of an Rf gene means that the  $F_1$  generation will not be completely or partially sterile, so that either self-pollination or cross pollination may occur. Self pollination of the  $F_1$  generation to produce several subsequent generations is important to ensure that a desired trait is heritable and stable and that a new variety has been isolated.

An example of a *Brassica* plant which is cytoplasmic male sterile and used for breeding is ogura (OGU) cytoplasmic male sterile (Pellan-Delourme, et al., 1987). A fertility restorer for ogura cytoplasmic male sterile plants has been transferred from *Raphanus sativus* (radish) to *Brassica* by Instit. National de Recherche Agricole (INRA) in Rennes, France (Pelletier, et al., 1987). The restorer gene, Rf1 originating from radish, is described in WO 92/05251 and in Delourme, et al., (1991). Improved versions of this restorer have been developed. For example, see WO98/27806, oilseed *brassica* containing an improved fertility restorer gene for ogura cytoplasmic male sterility, which is hereby incorporated by reference.

Other sources and refinements of CMS sterility in canola include the Polima cytoplasmic male sterile plant, as well as those of U.S. Pat. No. 5,789,566, DNA sequence imparting cytoplasmic male sterility, mitochondrial genome, nuclear genome, mitochondria and plant containing said sequence and process for the preparation of hybrids; U.S. Pat. No. 5,973,233 Cytoplasmic male sterility system production canola hybrids; and WO97/02737 Cytoplasmic male sterility system producing canola hybrids; EP Patent Application Number 0 599042A Methods for introducing a fertility restorer gene and for producing  $F_1$  hybrids of *Brassica* plants thereby; U.S. Pat. No. 6,229,072 Cytoplasmic male sterility system production canola hybrids; U.S. Pat. No. 4,658,085 Hybridization using cytoplasmic male sterility, cytoplasmic herbicide tolerance, and herbicide tolerance from nuclear genes; all of which are incorporated herein for this purpose.

Promising advanced breeding lines commonly are tested and compared to appropriate standards in environments representative of the commercial target area(s). The best lines are candidates for new commercial lines; and those still deficient in a few traits may be used as parents to produce new populations for further selection.

For most traits the true genotypic value may be masked by other confounding plant traits or environmental factors. One method for identifying a superior plant is to observe its performance relative to other experimental plants and to one or more widely grown standard varieties. If a single observation is inconclusive, replicated observations provide a better estimate of the genetic worth.

Proper testing should detect any major faults and establish the level of superiority or improvement over current varieties. In addition to showing superior performance, there must be a demand for a new variety that is compatible with industry standards or which creates a new market. The introduction of a new variety commonly will incur additional costs to the seed producer, the grower, the processor and the consumer, for special advertising and marketing, altered seed and commercial production practices, and new product utilization. The testing preceding release of a new variety should take into consideration research and development costs as well as tech-

nical superiority of the final variety. For seed-propagated varieties, it must be feasible to produce seed easily and economically.

These processes, which lead to the final step of marketing and distribution, usually take from approximately six to twelve years from the time the first cross is made. Therefore, the development of new varieties such as that of the present invention is a time-consuming process that requires precise forward planning, efficient use of resources, and a minimum of changes in direction.

Further, as a result of the advances in sterility systems, lines are developed that can be used as an open pollinated variety (i.e., a pureline cultivar sold to the grower for planting) and/or as a sterile inbred (female) used in the production of  $F_1$  hybrid seed. In the latter case, favorable combining ability with a restorer (male) would be desirable. The resulting hybrid seed would then be sold to the grower for planting.

The development of a canola hybrid in a canola plant breeding program involves three steps: (1) the selection of plants from various germplasm pools for initial breeding crosses; (2) the selfing of the selected plants from the breeding crosses for several generations to produce a series of inbred lines, which, although different from each other, breed true and are highly uniform; and (3) crossing the selected inbred lines with different inbred lines to produce the hybrids. During the inbreeding process in canola, the vigor of the lines decreases. Vigor is restored when two different inbred lines are crossed to produce the hybrid. An important consequence of the homozygosity and homogeneity of the inbred lines is that the hybrid between a defined pair of inbreds will always be the same. Once the inbreds that give a superior hybrid have been identified, the hybrid seed can be reproduced indefinitely as long as the homogeneity of the inbred parents is maintained.

Combining ability of a line, as well as the performance of the line per se, is a factor in the selection of improved canola lines that may be used as inbreds. Combining ability refers to a line's contribution as a parent when crossed with other lines to form hybrids. The hybrids formed for the purpose of selecting superior lines are designated test crosses. One way of measuring combining ability is by using breeding values. Breeding values are based on the overall mean of a number of test crosses. This mean is then adjusted to remove environmental effects and it is adjusted for known genetic relationships among the lines.

Hybrid seed production requires inactivation of pollen produced by the female parent. Incomplete inactivation of the pollen provides the potential for self-pollination. This inadvertently self-pollinated seed may be unintentionally harvested and packaged with hybrid seed. Similarly, because the male parent is grown next to the female parent in the field, there is also the potential that the male selfed seed could be unintentionally harvested and packaged with the hybrid seed. Once the seed from the hybrid bag is planted, it is possible to identify and select these self-pollinated plants. These self-pollinated plants will be genetically equivalent to one of the inbred lines used to produce the hybrid. Though the possibility of inbreds being included in hybrid seed bags exists, the occurrence is rare because much care is taken to avoid such inclusions. These self-pollinated plants can be identified and selected by one skilled in the art, through either visual or molecular methods.

*Brassica napus* canola plants, absent the use of sterility systems, are recognized to commonly be self-fertile with approximately 70 to 90 percent of the seed normally forming as the result of self-pollination. The percentage of cross pollination may be further enhanced when populations of recog-

nized insect pollinators at a given growing site are greater. Thus open pollination is often used in commercial canola production.

Currently *Brassica napus* canola is being recognized as an increasingly important oilseed crop and a source of meal in many parts of the world. The oil as removed from the seeds commonly contains a lesser concentration of endogenously formed saturated fatty acids than other vegetable oils and is well suited for use in the production of salad oil or other food products or in cooking or frying applications. The oil also finds utility in industrial applications. Additionally, the meal component of the seeds can be used as a nutritious protein concentrate for livestock.

Canola oil has the lowest level of saturated fatty acids of all vegetable oils. "Canola" refers to rapeseed (*Brassica*) which (1) has an erucic acid ( $C_{22:1}$ ) content of at most 2 percent by weight based on the total fatty acid content of a seed, preferably at most 0.5 percent by weight and most preferably essentially 0 percent by weight; and (2) produces, after crushing, an air-dried meal containing less than 30 micromoles ( $\mu\text{mol}$ ) glucosinolates per gram of defatted (oil-free) meal. These types of rapeseed are distinguished by their edibility in comparison to more traditional varieties of the species.

*Sclerotinia* infects over 100 species of plants, including numerous economically important crops such as *Brassica* species, sunflowers, dry beans, soybeans, field peas, lentils, lettuce, and potatoes (Boland and Hall, 1994). *Sclerotinia sclerotiorum* is responsible for over 99% of *Sclerotinia* disease, while *Sclerotinia minor* produces less than 1% of the disease. *Sclerotinia* produces sclerotia, irregularly-shaped, dark overwintering bodies, which can endure in soil for four to five years. The sclerotia can germinate carpogenically or myceliogenically, depending on the environmental conditions and crop canopies. The two types of germination cause two distinct types of diseases. Sclerotia that germinate carpogenically produce apothecia and ascospores that infect above-ground tissues, resulting in stem blight, stalk rot, head rot, pod rot, white mold and blossom blight of plants. Sclerotia that germinate myceliogenically produce mycelia that infect root tissues, causing crown rot, root rot and basal stalk rot.

*Sclerotinia* causes *Sclerotinia* stem rot, also known as white mold, in *Brassica*, including canola. Canola is a type of *Brassica* having a low level of glucosinolates and erucic acid in the seed. The sclerotia germinate carpogenically in the summer, producing apothecia. The apothecia release wind-borne ascospores that travel up to one kilometer. The disease is favoured by moist soil conditions (at least 10 days at or near field capacity) and temperatures of 15-25° C., prior to and during canola flowering. The spores cannot infect leaves and stems directly; they must first land on flowers, fallen petals, and pollen on the stems and leaves. Petal age affects the efficiency of infection, with older petals more likely to result in infection (Heran, et al., 1999). The fungal spores use the flower parts as a food source as they germinate and infect the plant.

The severity of *Sclerotinia* in *Brassica* is variable, and is dependent on the time of infection and climatic conditions (Heran, et al., 1999). The disease is favored by cool temperatures and prolonged periods of precipitation. Temperatures between 20 and 25° C. and relative humidities of greater than 80% are required for optimal plant infection (Heran, et al., 1999). Losses ranging from 5 to 100% have been reported for individual fields (Manitoba Agriculture, Food and Rural Initiatives, 2004). On average, yield losses are estimated to be 0.4 to 0.5 times the *Sclerotinia Sclerotiorum* Field Severity score, a rating based on both percentage infection and disease

severity. More information is provided herein at Example 2. For example, if a field has 20% infection (20/100 plants infected), then the yield loss would be about 10% provided plants are dying prematurely due to the infection of the main stem (rating 5-SSFS=20%). If the plants are affected much less (rating 1-SSFS=4%), yield loss is reduced accordingly. Further, *Sclerotinia* can cause heavy losses in wet swaths. *Sclerotinia sclerotiorum* caused economic losses to canola growers in Minnesota and North Dakota of 17.3, 20.8, and 16.8 million dollars in 1999, 2000 and 2001, respectively (Bradley, et al. 2006). In Canada, this disease is extremely important in Southern Manitoba, parts of South Central Alberta and also in Eastern areas of Saskatchewan. Since weather plays an important role in development of this disease, its occurrence is irregular and unpredictable. Certain reports estimate about 0.8 to 1.3 million acres of canola being sprayed with fungicide in Southern Manitoba annually. The fungicide application costs about \$25 per acre, which represents a significant cost for canola producers. Moreover, producers may decide to apply fungicide based on the weather forecast, while later changes in the weather pattern discourage disease development, resulting in wasted product, time, and fuel. Creation of *sclerotinia* tolerant canola cultivars has been an important goal for many of the Canadian canola breeding organizations.

No canola cultivar carrying an improved level of genetic resistance to *Sclerotinia* has previously been released in Canada. 45S52 is the first canola hybrid cultivar having this improved level of *sclerotinia* tolerance. The *sclerotinia* tolerance in 45S52 comes from parents developed by conventional plant breeding techniques of crossing and selection. The parental lines were developed and screened in a field screening nursery which was inoculated to ensure high and consistent *Sclerotinia* disease pressure. See, for example, the methods described in PCT publication WO2006/135717.

Since canola variety 45S52 is a hybrid produced from substantially homogeneous parents, it can be reproduced by planting seeds of such parents, growing the resulting canola plants under controlled pollination conditions with adequate isolation so that cross-pollination occurs between the parents, and harvesting the resulting hybrid seed using conventional agronomic practices.

The symptoms of *Sclerotinia* infection usually develop several weeks after flowering begins. The plants develop pale-grey to white lesions, at or above the soil line and on upper branches and pods. The infections often develop where the leaf and the stem join because the infected petals lodge there. Once plants are infected, the mold continues to grow into the stem and invade healthy tissue. Infected stems appear bleached and tend to shred. Hard black fungal sclerotia develop within the infected stems, branches, or pods. Plants infected at flowering produce little or no seed. Plants with girdled stems wilt and ripen prematurely. Severely infected crops frequently lodge, shatter at swathing, and make swathing more time consuming. Infections can occur in all above-ground plant parts, especially in dense or lodged stands, where plant-to-plant contact facilitates the spread of infection. New sclerotia carry the disease over to the next season.

Conventional methods for control of *Sclerotinia* diseases include (a) chemical control, (b) disease resistance and (c) cultural control, each of which is described below.

(a) Fungicides such as benomyl, vinclozolin and iprodione remain the main method of control of *Sclerotinia* disease (Morall, et al., 1985; Tu, 1983). Recently, additional fungicidal formulations have been developed for use against *Sclerotinia*, including azoxystrobin, prothioconazole, and boscalid. (Johnson, 2005) However, use of fungicide is expensive

and can be harmful to the user and environment. Further, resistance to some fungicides has occurred due to repeated use.

(b) In certain cultivars of bean, safflower, sunflower and soybean, some progress has been made in developing partial (incomplete) resistance. Partial resistance is often referred to as tolerance. However, success in developing partial resistance has been very limited, probably because partial physiological resistance is a multigene trait as demonstrated in bean (Fuller, et al., 1984). In addition to partial physiological resistance, some progress has been made to breed for morphological traits to avoid *Sclerotinia* infection, such as upright growth habit, lodging resistance and narrow canopy. For example, bean plants with partial physiological resistance and with an upright stature, narrow canopy and indeterminate growth habit were best able to avoid *Sclerotinia* (Saindon, et al., 1993). Early maturing cultivars of safflower showed good field resistance to *Sclerotinia*. Finally, in soybean, cultivar characteristics such as height, early maturity and great lodging resistance result in less disease, primarily because of a reduction of favorable microclimate conditions for the disease. (Boland and Hall, 1987; Buzzell, et al. 1993)

(c) Cultural practices, such as using pathogen-free or fungicide-treated seed, increasing row spacing, decreasing seeding rate to reduce secondary spread of the disease, and burying sclerotia to prevent carpogenic germination, may reduce *Sclerotinia* disease but not effectively control the disease.

All Canadian canola genotypes are susceptible to *Sclerotinia* stem rot (Manitoba Agriculture, Food and Rural Initiatives, 2004). This includes all known spring petalled genotypes of canola quality. There is also no resistance to *Sclerotinia* in Australian canola varieties. (Hind-Lanoiselet, et al. 2004). Some varieties with certain morphological traits are better able to withstand *Sclerotinia* infection. For example, Polish varieties (*Brassica rapa*) have lighter canopies and seem to have much lower infection levels. In addition, petal-less varieties (apetalous varieties) avoid *Sclerotinia* infection to a greater extent (Okuyama, et al., 1995; Fu, 1990). Other examples of morphological traits which confer a degree of reduced field susceptibility in *Brassica* genotypes include increased standability, reduced petal retention, branching (less compact and/or higher), and early leaf abscission. Jurke and Fernando, (2003) screened eleven canola genotypes for *Sclerotinia* disease incidence. Significant variation in disease incidence was explained by plant morphology, and the difference in petal retention was identified as the most important factor. However, these morphological traits alone do not confer resistance to *Sclerotinia*, and all canola products in Canada are considered susceptible to *Sclerotinia*.

Winter canola genotypes are also susceptible to *Sclerotinia*. In Germany, for example, no *Sclerotinia*-resistant varieties are available. (Specht, 2005) The widely-grown German variety Express is considered susceptible to moderately susceptible and belongs to the group of less susceptible varieties/hybrids.

Spraying with fungicide is the only means of controlling *Sclerotinia* in canola crops grown under disease-favorable conditions at flowering. Typical fungicides used for controlling *Sclerotinia* on *Brassica* include Rovral™/Proline™ from Bayer and Ronilan™/Lance™ from BASF. The active ingredient in Lance™ is Boscalid, and it is marketed as Endura™ in the United States. The fungicide should be applied before symptoms of stem rot are visible and usually at the 20-30% bloom stage of the crop. If infection is already evident, there is no use in applying fungicide as it is too late to have an effect. Accordingly, growers must assess their fields

for disease risk to decide whether to apply a fungicide. This can be done by using a government provided checklist or by using a petal testing kit. Either method is cumbersome and prone to errors. (Hind-Lanoiselet, 2004; Johnson, 2005)

Numerous efforts have been made to develop *Sclerotinia* resistant *Brassica* plants. Built-in resistance would be more convenient, economical, and environmentally-friendly than controlling *Sclerotinia* by application of fungicides. Since the trait is polygenic it would be stable and not prone to loss of efficacy, as fungicides may be.

## DEFINITIONS

In the description and tables which follow, a number of terms are used. In order to aid in a clear and consistent understanding of the specification, the following definitions and evaluation criteria are provided.

**Anther Fertility.** The ability of a plant to produce pollen 1=sterile, 2=all anthers shedding pollen (vs. Pollen Formation which is amount of pollen produced).

**Anther Arrangement.** The general disposition of the anthers in typical fully opened flowers is observed.

**Chlorophyll Content.** The typical chlorophyll content of the mature seeds is determined by using methods recommended by the Western Canada

Canola/Rapeseed Recommending Committee (WCC/RRC) and is considered to be low if <8 ppm, medium if 8 to 15 ppm, and high if >15 ppm. Also, chlorophyll could be analyzed using NIR (Near Infra Red spectroscopy) as long as the instrument is calibrated according to the manufacturer's specifications.

**Cotyledon.** A cotyledon is a part of the embryo within the seed of a plant; it is also referred to as a seed leaf. Upon germination, the cotyledon may become the embryonic first leaf of a seedling.

**Cotyledon Length.** The distance between the indentation at the top of the cotyledon and the point where the width of the petiole is approximately 4 mm.

**Cotyledon Width.** The width at the widest point of the cotyledon when the plant is at the two- to three-leaf stage of development.

**Disease Resistance:** Resistance to various diseases is evaluated and is expressed on a scale of 0=highly resistant, 5=highly susceptible. The WCC/RRC blackleg classification is based on % severity index described as follows:

0-30%=Resistant  
30%-50%=Moderately Resistant  
50%-70%=Moderately Susceptible  
70%-90%=Susceptible  
>90%=Highly susceptible.

The % severity index=blackleg rating on 0-5 for a variety/blackleg rating for HS variety Westar.

*Sclerotinia* scoring is described in Example 2 herein.

**Erucic Acid Content:** The percentage of the fatty acids in the form of C22:1 as determined by one of the methods recommended by the WCC/RRC, being AOCS Official Method Ce 2-66 Preparation of Methyl esters of Long-Chain Fatty Acids or AOCS Official Method Ce 1-66 Fatty Acid Composition by Gas Chromatography.

**Fatty Acid Content:** The typical percentages by weight of fatty acids present in the endogenously formed oil of the mature whole dried seeds are determined. During such determination the seeds are crushed and are extracted as fatty acid methyl esters following reaction with methanol and sodium methoxide. Next the resulting ester is analyzed for fatty acid content by gas liquid chromatography using a capillary col-

umn which allows separation on the basis of the degree of unsaturation and fatty acid chain length. This procedure is described in the work of Daun, et al., (1983) *J. Amer. Oil Chem. Soc.* 60:1751 to 1754 which is herein incorporated by reference.

Flower Bud Location. A determination is made whether typical buds are disposed above or below the most recently opened flowers.

Flower Date 50%. (Same as Time to flowering) The number of days from planting until 50% of the plants in a planted area have at least one open flower.

Flower Petal Coloration. The coloration of open exposed petals on the first day of flowering is observed.

Frost Tolerance (Spring Type Only). The ability of young plants to withstand late spring frosts at a typical growing area is evaluated and is expressed on a scale of 1 (poor) to 5 (excellent).

Gene Silencing. The interruption or suppression of the expression of a gene at the level of transcription or translation.

Genotype. Refers to the genetic constitution of a cell or organism.

Glucosinolate Content. The total glucosinolates of seed at 8.5% moisture, as measured by AOCS Official Method AK-1-92 (determination of glucosinolates content in rapeseed—colza by HPLC), is expressed as micromoles per gram of defatted, oil-free meal. Capillary gas chromatography of the trimethylsilyl derivatives of extracted and purified desulfo-glucosinolates with optimization to obtain optimum indole glucosinolate detection is described in “*Procedures of the Western Canada Canola/Rapeseed Recommending Committee Incorporated for the Evaluation and Recommendation for Registration of Canola/Rapeseed Candidate Cultivars in Western Canada*”. Also, glucosinolates could be analyzed using NIR (Near Infra Red spectroscopy) as long as the instrument is calibrated according to the manufacturer’s specifications.

Grain. Seed produced by the plant or a self or sib of the plant that is intended for food or feed use.

Green Seed. The number of seeds that are distinctly green throughout as defined by the Canadian Grain Commission. Expressed as a percentage of seeds tested.

Herbicide Resistance. Resistance to various herbicides when applied at standard recommended application rates is expressed on a scale of 1 (resistant), 2 (tolerant), or 3 (susceptible).

Leaf Anthocyanin Coloration. The presence or absence of leaf anthocyanin coloration, and the degree thereof if present, are observed when the plant has reached the 9- to 11-leaf stage.

Leaf Attachment to Stem. The presence or absence of clasping where the leaf attaches to the stem, and when present the degree thereof, are observed.

Leaf Attitude. The disposition of typical leaves with respect to the petiole is observed when at least 6 leaves of the plant are formed.

Leaf Color. The leaf blade coloration is observed when at least 6 leaves of the plant are completely developed.

Leaf Glaucoity. The presence or absence of a fine whitish powdery coating on the surface of the leaves, and the degree thereof when present, are observed.

Leaf Length. The length of the leaf blades and petioles are observed when at least 6 leaves of the plant are completely developed.

Leaf Lobes. The fully developed upper stem leaves are observed for the presence or absence of leaf lobes when at least 6 leaves of the plant are completely developed.

Leaf Margin Depth. A rating of the depth of the dentations along the upper third of the margin of the largest leaf. 1=very shallow, 9=very deep.

Leaf Margin Hairiness. The leaf margins of the first leaf are observed for the presence or absence of pubescence, and the degree thereof, when the plant is at the two leaf-stage.

Leaf Margin Type. A visual rating of the dentations along the upper third of the margin of the largest leaf. 1=undulating, 2=rounded, 3=sharp.

Leaf Surface. The leaf surface is observed for the presence or absence of wrinkles when at least 6 leaves of the plant are completely developed.

Leaf Tip Reflexion. The presence or absence of bending of typical leaf tips and the degree thereof, if present, are observed at the 6 to 11 leaf-stage.

Leaf Upper Side Hairiness. The upper surfaces of the leaves are observed for the presence or absence of hairiness, and the degree thereof if present, when at least 6 leaves of the plant are formed.

Leaf Width. The width of the leaf blades is observed when at least 6 leaves of the plant are completely developed.

Length of Beak. The typical length of the silique beak when mature is observed and is expressed on a scale of 1 (very short) to 9 (very long).

Locus. A defined segment of DNA.

Locus Conversion. A locus conversion refers to plants within a variety that have been modified in a manner that retains the overall genetics of the variety and further comprises one or more loci with a specific desired trait, such as male sterility, insect, disease or herbicide resistance. Examples of single locus conversions include mutant genes, transgenes and native traits finely mapped to a single locus. One or more locus conversion traits may be introduced into a single canola variety.

Maturity. The number of days from planting to maturity is observed, with maturity being defined as the plant stage when pods with seed change color, occurring from green to brown or black, on the bottom third of the pod-bearing area of the main stem.

Number of Leaf Lobes. The frequency of leaf lobes, when present, is observed when at least 6 leaves of the plant are completely developed.

Oil Content. The typical percentage by weight oil present in the mature whole dried seeds is determined by ISO 10565: 1993 Oilseeds Simultaneous determination of oil and water—Pulsed NMR method. Also, oil could be analyzed using NIR (Near Infra Red spectroscopy) as long as the instrument is calibrated according to the manufacturer’s specifications, reference AOCS Procedure Am 1-92 Determination of Oil, Moisture and Volatile Matter, and Protein by Near-Infrared Reflectance.

Pedicle Length. The typical length of the silique stem when mature is observed and is expressed on a scale of 1 (very short) to 9 (very long).

Petal Length. The lengths of typical petals of fully opened flowers are observed.

Petal Width. The widths of typical petals of fully opened flowers are observed.

Petiole Length. The length of the petioles is observed, in a line forming lobed leaves, when at least 6 leaves of the plant are completely developed.

Plant Height. The overall plant height at the end of flowering is observed.

Ploidy. This refers to the number of chromosomes exhibited by the line, for example diploid or tetraploid.

## 13

Pod Anthocyanin Coloration. The presence or absence at maturity of silique anthocyanin coloration, and the degree thereof if present, are observed.

Pod Habit. The typical manner in which the siliques are borne on the plant at maturity is observed.

Pod Length. The typical silique length is observed and is expressed on a scale of 1 (very short) to 9 (very long).

Pod Attitude. A visual rating of the angle joining the pedicel to the pod at maturity. 1=erect, 3=semi-erect, 5=horizontal, 7=semi-drooping and 9=drooping.

Pod Type. The overall configuration of the silique is observed.

Pod Width. The typical pod width when mature is observed and is expressed on a scale of 1 (very narrow) to 9 (very wide).

Pollen Formation. The relative level of pollen formation is observed at the time of dehiscence.

Protein Content: The typical percentage by weight of protein in the oil free meal of the mature whole dried seeds is determined by AOCS Official Method Ba 4e-93 Combustion Method for the Determination of Crude Protein. Also, protein could be analyzed using NIR (Near Infra Red spectroscopy) as long as the instrument is calibrated according to the manufacturer's specifications, reference AOCS Procedure Am 1-92 Determination of Oil, Moisture and Volatile Matter, and Protein by Near-Infrared Reflectance.

Resistance. The ability of a plant to withstand exposure to an insect, disease, herbicide or other condition. A resistant plant variety or hybrid will have a level of resistance higher than a comparable wild-type variety or hybrid. "Tolerance" is a term commonly used in crops affected by *Sclerotinia*, such as canola, soybean, and sunflower, and is used to describe an improved level of field resistance.

Resistant to Lodging. Resistance to lodging at maturity is expressed on a scale of 1 (weak) to 9 (strong).

Resistance to Shattering. Resistance to silique shattering is observed at seed maturity and is expressed on a scale of 1 (poor) to 9 (excellent).

Root Anthocyanin Coloration. The presence or absence of anthocyanin coloration in the skin at the top of the root is observed when the plant has reached at least the six-leaf stage.

Root Anthocyanin Expression. When anthocyanin coloration is present in skin at the top of the root, it further is observed for the exhibition of a reddish or bluish cast within such coloration when the plant has reached at least the six-leaf stage.

Root Anthocyanin Streaking. When anthocyanin coloration is present in the skin at the top of the root, it further is observed for the presence or absence of streaking within such coloration when the plant has reached at least the six-leaf stage.

Root Chlorophyll Coloration. The presence or absence of chlorophyll coloration in the skin at the top of the root is observed when the plant has reached at least the six-leaf stage.

Root Coloration Below Ground. The coloration of the root skin below ground is observed when the plant has reached at least the six-leaf stage.

Root Depth in Soil. The typical root depth is observed when the plant has reached at least the six-leaf stage.

Root Flesh Coloration. The internal coloration of the root flesh is observed when the plant has reached at least the six-leaf stage.

Seedling Growth Habit. The growth habit of young seedlings is observed for the presence of a weak (1) or strong (9) rosette character and is expressed on a scale of 1 to 9.

Seeds Per Pod. The average number of seeds per pod is observed.

## 14

Seed Coat Color. The seed coat color of typical mature seeds is observed.

Seed Coat Mucilage. The presence or absence of mucilage on the seed coat is determined and is expressed on a scale of 1 (absent) to 9 (heavy). During such determination a petri dish is filled to a depth of 0.3 cm. with tap water provided at room temperature. Seeds are added to the petri dish and are immersed in water where they are allowed to stand for five minutes. The contents of the petri dish containing the immersed seeds next is examined under a stereo microscope equipped with transmitted light. The presence of mucilage and the level thereof is observed as the intensity of a halo surrounding each seed.

Seed Size. The weight in grams of 1,000 typical seeds is determined at maturity while such seeds exhibit a moisture content of approximately 5 to 6 percent by weight.

Speed of Root Formation. The typical speed of root formation is observed when the plant has reached the 4- to 11-leaf stage.

Stem Anthocyanin Coloration. The presence or absence of leaf anthocyanin coloration and the intensity thereof, if present, are observed when the plant has reached the 9- to 11-leaf stage.

Stem Lodging at Maturity. A visual rating of a plant's ability to resist stem lodging at maturity. 1=very weak (lodged), 9=very strong (erect).

Time to Flowering. A determination is made of the number of days when at least 50 percent of the plants have one or more open buds on a terminal raceme in the year of sowing.

Seasonal Type. This refers to whether the new line is considered to be primarily a Spring or Winter type of canola.

Winter Survival (Winter Type Only). The ability to withstand winter temperatures at a typical growing area is evaluated and is expressed on a scale of 1 (poor) to 5 (excellent).

45S52 is a fully restored spring *Brassica napus* hybrid with the glyphosate tolerance gene, based on OGU INRA system. It was developed at Georgetown Research Centre of Pioneer Hi-Bred Production LP (subsidiary of Pioneer Hi-Bred International Inc.). It is a single cross hybrid produced by crossing a female parent (male sterile inbred-A line) x maintainer inbred-B line) carrying the glyphosate tolerance gene by a restorer—R male line, where A and B lines are genetically alike except A line carries the OGU INRA cytoplasm, while B line carries the normal *B. napus* cytoplasm.

The maintainer line-B line was developed using pedigree selection from a bi-parental cross where one parent contributed glyphosate resistance while the other parent contributed *sclerotinia* tolerance. The last crossing was completed in 2003. The F1s were grown in the greenhouse to produce F2 seed. The F2 was planted and evaluated in 2008 breeding nursery. The remnant F2 was planted in the greenhouse and the F2 single plants were screened for blackleg tolerance and glyphosate tolerance and *sclerotinia* tolerance in the greenhouse. The F3s were also planted in the GH and were screened for glyphosate tolerance. The F4 progenies were evaluated in Ontario evaluation nursery and *sclerotinia* nursery. Based on the selection in the evaluation nursery for glyphosate tolerance, early maturity, lodging resistance, high oil and protein, general vigor and uniformity and selection in the *sclerotinia* nursery, a line was selected and F5 seed was assigned new number. Backcrossing was carried out in the greenhouse to transfer the OGU INRA cytoplasm starting at F6 generation. Breeder Seed for the A line was bulked at BC6.

The Restorer line—R—was developed from BC1 using pedigree selection. The first backcross was completed in 2004. The BC1 and BC1 S1 and BC1 S2 plants were grown in successive three generations in GH and were screened for

## 15

blackleg and/or *sclerotinia*. The BC1 S3s were then evaluated in Ontario evaluation nursery and *Sclerotinia* nursery. The BC1S4 were sent to Chile for generation advancement. The BC1S5s were again evaluated in Ontario restorer nursery and *Sclerotinia* nursery. During both years of Ontario nursery evaluation, the lines were selected for general vigor, uniformity, days to maturity, oil %, and protein %, glucosinolates, total saturates, etc. In the *Sclerotinia* nurseries, the lines were selected for *sclerotinia* tolerance. The BC1S5 based testcross hybrids were evaluated at six locations and one of them was assigned permanent code. The Breeder Seed of the male line was bulked at BC1S7.

Varietal Characteristics (See also Tables 1, 2, 3, )	
Seed Yield:	Nineteen percent higher than WCC/RRC checks.
Disease Reaction:	Classified as Moderately Resistant to blackleg ( <i>Leptosphaera maculans</i> ) according to WCC/RRC guidelines (Table 3). Based on Pioneer Hi-Bred trials, 45S52 is also resistant (R) to <i>Fusarium</i> wilt. 45S52 has substantially improved tolerance to white mold ( <i>Sclerotinia sclerotiorum</i> Lib) compared to a susceptible check 45H26. (See Example 4.)
Plant Height:	Approximately 5 cm taller than WCC/RRC checks
Maturity:	Slightly earlier maturing than WCC/RRC checks.
Lodging:	Similar to mean of checks
Herbicide tolerance:	Tolerant to glyphosate herbicides; field test confirms that 45S52 tolerates the recommended rate of glyphosate (1.5L/ha) without showing plant injury or any significant negative effect on yield, agronomic and quality traits (Table 2).
Variants:	This variety exhibits less than 1500/10,000 (<15% glyphosate - susceptible plants).
Seed Characteristics:	
Seed color:	Dark brown
Grain size:	1000 seed weight is slightly greater than mean of the checks
Seed oil content:	2.0% higher than mean of the checks.
Seed protein content:	2.9% lower than mean of the checks.
Erucic acid:	Less than 0.5% (maximum allowable limit).
Total saturates:	0.05% higher than mean of the checks
Total glucosinolates:	4.0 umol/g lower than mean of the checks
Chlorophyll:	8 ppm lower than mean of the checks.
Summary:	45S52 (08N775R) is a medium maturing, high yielding glyphosate resistant <i>Brassica napus</i> canola hybrid having moderately resistant "MR" rating for blackleg and resistant "R" rating for <i>Fusarium</i> wilt. It has a very high oil contents which is 2.0% higher than mean of the checks. Its protein and chlorophyll contents are lower than the checks.
Inbred maintenance:	Pioneer Hi-Bred Production LP
Canadian distributor:	Pioneer Hi-Bred Production LP.
Status:	It has completed two years in Western Canadian trials (2008: 1 <sup>st</sup> year and 2009: 2 <sup>nd</sup> year). This hybrid met all the minimum standards except for the protein. WCC/RRC set aside the protein requirements and supported this hybrid for registration.

A canola hybrid needs to be homogenous and reproducible to be useful for the production of a commercial crop on a reliable basis. There are a number of analytical methods available to determine the phenotypic stability of a canola hybrid.

The oldest and most traditional method of analysis is the observation of phenotypic traits. The data are usually collected in field experiments over the life of the canola plants to be examined. Phenotypic characteristics most often are observed for traits associated with seed yield, seed oil content, seed protein content, fatty acid composition of oil, glucosinolate content of meal, growth habit, lodging resistance, plant height, shattering resistance, etc.

## 16

In addition to phenotypic observations, the genotype of a plant can also be examined. A plant's genotype can be used to identify plants of the same variety or a related variety. For example, the genotype can be used to determine the pedigree of a plant. There are many laboratory-based techniques available for the analysis, comparison and characterization of plant genotype; among these are Isozyme Electrophoresis, Restriction Fragment Length Polymorphisms (RFLPs), Randomly Amplified Polymorphic DNAs (RAPDs), Arbitrarily Primed Polymerase Chain Reaction (AP-PCR), DNA Amplification Fingerprinting (DAF), Sequence Characterized Amplified Regions (SCARs), Amplified Fragment Length Polymorphisms (AFLPs), Simple Sequence Repeats (SSRs) which are also referred to as Microsatellites, and Single Nucleotide Polymorphisms (SNPs).

The variety of the present invention has shown uniformity and stability for all traits, as described in the following variety description information. The variety has been increased with continued observation for uniformity.

45S52 is a high-yielding, glyphosate resistant *Brassica napus* canola hybrid having an "MR" resistance rating for blackleg. Its oil content is slightly higher than the mean of checks and protein is slightly lower than the WCC/RRC checks 46A65 and AWPQ2. Its seed size is a bit larger and has higher chlorophyll than the checks.

Table 1 provides data on morphological, agronomic, and quality traits for 45S52 and publicly-available canola variety 45S51. When preparing the detailed phenotypic information that follows, plants of the new 45S52 variety were observed while being grown using conventional agronomic practices. For comparative purposes, canola plants of publicly-available canola variety, 45S51, were similarly grown in a replicated experiment.

Observations were recorded on various morphological traits for the hybrid 45S52 and comparative check cultivars.

TABLE 1

VARIETY DESCRIPTIONS BASED ON MORPHOLOGICAL, AGRONOMIC AND QUALITY TRAITS					
Trait		45S52		45S51	
Code	Trait	Mean	Description	Mean	Description

Hybrid 45S52 can be advantageously used in accordance with the breeding methods described herein and those known in the art to produce hybrids and other progeny plants retaining desired trait combinations of 45S52. This invention is thus also directed to methods for producing a canola plant by crossing a first parent canola plant with a second parent canola plant wherein either the first or second parent canola plant is canola variety 45S52. Further, both first and second parent canola plants can come from the canola variety 45S52. Either the first or the second parent plant may be male sterile.

Still further, this invention also is directed to methods for producing a 45S52-derived canola plant by crossing canola variety 45S52 with a second canola plant and growing the progeny seed, and repeating the crossing and growing steps with the canola 45S52-derived plant from 1 to 2 times, 1 to 3 times, 1 to 4 times, or 1 to 5 times. Thus, any such methods using the canola variety 45S52 are part of this invention: open pollination, selfing, backcrosses, hybrid production, crosses to populations, and the like. All plants produced using canola variety 45S52 as a parent are within the scope of this invention, including plants derived from canola variety 45S52. This includes canola lines derived from 45S52 which include components for either male sterility or for restoration of fertility. Advantageously, the canola variety is used in crosses with other, different, canola plants to produce first generation (F<sub>1</sub>) canola hybrid seeds and plants with superior characteristics.

The invention also includes a single-gene conversion of 45S52. A single-gene conversion occurs when DNA sequences are introduced through traditional (non-transformation) breeding techniques, such as backcrossing. DNA sequences, whether naturally occurring or transgenes, may be introduced using these traditional breeding techniques. Desired traits transferred through this process include, but are not limited to, fertility restoration, fatty acid profile modification, other nutritional enhancements, industrial enhancements, disease resistance, insect resistance, herbicide resistance and yield enhancements. The trait of interest is transferred from the donor parent to the recurrent parent, in this case, the canola plant disclosed herein. Single-gene traits may result from the transfer of either a dominant allele or a recessive allele. Selection of progeny containing the trait of interest is done by direct selection for a trait associated with a dominant allele. Selection of progeny for a trait that is transferred via a recessive allele will require growing and selfing the first backcross to determine which plants carry the recessive alleles. Recessive traits may require additional progeny testing in successive backcross generations to determine the presence of the gene of interest.

It should be understood that the canola variety of the invention can, through routine manipulation by cytoplasmic genes, nuclear genes, or other factors, be produced in a male-sterile or restorer form as described in the references discussed earlier. Such embodiments are also within the scope of the present claims. Canola variety 45S52 can be manipulated to be male sterile by any of a number of methods known in the art, including by the use of mechanical methods, chemical methods, SI, CMS (either ogura or another system) or NMS. The term "manipulated to be male sterile" refers to the use of any available techniques to produce a male sterile version of canola variety 45S52. The male sterility may be either partial or complete male sterility. This invention is also directed to F1 hybrid seed and plants produced by the use of Canola variety 45S52. Canola variety 45S52 can also further comprise a component for fertility restoration of a male sterile plant, such as an Rf restorer gene. In this case, canola variety 45S52 could then be used as the male plant in hybrid seed production.

This invention is also directed to the use of 45S52 in tissue culture. As used herein, the term plant includes plant protoplasts, plant cell tissue cultures from which canola plants can be regenerated, plant calli, plant clumps, and plant cells that are intact in plants or parts of plants, such as embryos, pollen, ovules, seeds, flowers, kernels, ears, cobs, leaves, husks, stalks, roots, root tips, anthers, silk and the like. Pauls, et al., (2006) (*Canadian J of Botany* 84(4):668-678) confirmed that tissue culture as well as microspore culture for regeneration of canola plants can be accomplished successfully. Chuong, et al., (1985) "A Simple Culture Method for *Brassica* Hypocotyl Protoplasts", *Plant Cell Reports* 4:4-6; Barsby, et al., (Spring 1996) "A Rapid and Efficient Alternative Procedure for the Regeneration of Plants from Hypocotyl Protoplasts of *Brassica napus*", *Plant Cell Reports*; Kartha, et al., (1974) "In vitro Plant Formation from Stem Explants of Rape", *Physiol. Plant* 31:217-220; Narasimhulu, et al., (Spring 1988) "Species Specific Shoot Regeneration Response of Cotyledonary Explants of *Brassicas*", *Plant Cell Reports*; Swanson, (1990) "Microspore Culture in *Brassica*", *Methods in Molecular Biology* 6(17):159; "Cell Culture techniques and Canola improvement" *J. Am. Oil Chem. Soc.* 66(4):455-56 (1989). Thus, it is clear from the literature that the state of the art is such that these methods of obtaining plants are, and were, "conventional" in the sense that they are routinely used and have a very high rate of success.

The utility of canola variety 45S52 also extends to crosses with other species. Commonly, suitable species will be of the family Brassicaceae.

The advent of new molecular biological techniques has allowed the isolation and characterization of genetic elements with specific functions, such as encoding specific protein products. Scientists in the field of plant biology developed a strong interest in engineering the genome of plants to contain and express foreign genetic elements, or additional, or modified versions of native or endogenous genetic elements in order to alter the traits of a plant in a specific manner. Any DNA sequences, whether from a different species, or from the same species that are inserted into the genome using transformation are referred to herein collectively as "transgenes". Over the last fifteen to twenty years several methods for producing transgenic plants have been developed, and the present invention, in particular embodiments, also relates to transformed versions of the claimed canola variety 45S52.

Numerous methods for plant transformation have been developed, including biological and physical plant transformation protocols. See, for example, Miki, et al., "Procedures for Introducing Foreign DNA into Plants" in *Methods in Plant Molecular Biology and Biotechnology*, Glick, and Genetic Transformation for the improvement of Canola World Conf, Biotechnol. Fats and Oils Ind. 43-46 (1988). In addition, expression vectors and in vitro culture methods for plant cell or tissue transformation and regeneration of plants are available. See, for example, Gruber, et al., "Vectors for Plant Transformation" in *Methods in Plant Molecular Biology and Biotechnology*, Glick and Thompson, Eds. (CRC Press, Inc., Boca Raton, 1993) pages 89-119.

The most prevalent types of plant transformation involve the construction of an expression vector. Such a vector comprises a DNA sequence that contains a gene under the control of or operatively linked to a regulatory element, for example a promoter. The vector may contain one or more genes and one or more regulatory elements.

A genetic trait which has been engineered into a particular canola plant using transformation techniques, could be moved into another line using traditional breeding techniques that are well known in the plant breeding arts. For example, a backcrossing approach could be used to move a transgene from a transformed canola plant to an elite inbred line and the resulting progeny would comprise a transgene. Also, if an inbred line was used for the transformation then the transgenic plants could be crossed to a different line in order to produce a transgenic hybrid canola plant. As used herein, "crossing" can refer to a simple X by Y cross, or the process of backcrossing, depending on the context. Various genetic elements can be introduced into the plant genome using transformation. These elements include but are not limited to genes; coding sequences; inducible, constitutive, and tissue specific promoters; enhancing sequences; and signal and targeting sequences. See, U.S. Pat. No. 6,222,101 which is herein incorporated by reference.

With transgenic plants according to the present invention, a foreign protein can be produced in commercial quantities. Thus, techniques for the selection and propagation of transformed plants, which are well understood in the art, yield a plurality of transgenic plants which are harvested in a conventional manner, and a foreign protein then can be extracted from a tissue of interest or from total biomass. Protein extraction from plant biomass can be accomplished by known methods which are discussed, for example, by Heney and Orr, (1981) *Anal. Biochem.* 114:92-96.

A genetic map can be generated, primarily via conventional Restriction Fragment Length Polymorphisms (RFLP),

Polymerase Chain Reaction (PCR) analysis, and Simple Sequence Repeats (SSR), which identifies the approximate chromosomal location of the integrated DNA molecule coding for the foreign protein. For exemplary methodologies in this regard, see, Glick and Thompson, METHODS IN PLANT MOLECULAR BIOLOGY AND BIOTECHNOLOGY 269-284 (CRC Press, Boca Raton, 1993). Map information concerning chromosomal location is useful for proprietary protection of a subject transgenic plant. If unauthorized propagation is undertaken and crosses made with other germplasm, the map of the integration region can be compared to similar maps for suspect plants, to determine if the latter have a common parentage with the subject plant. Map comparisons would involve hybridizations, RFLP, PCR, SSR and sequencing, all of which are conventional techniques.

Likewise, by means of the present invention, plants can be genetically engineered to express various phenotypes of agronomic interest. Exemplary transgenes implicated in this regard include, but are not limited to, those categorized below. 1. Genes that Confer Resistance to Pests or Disease and that Encode:

(A) Plant disease resistance genes. Plant defenses are often activated by specific interaction between the product of a disease resistance gene (R) in the plant and the product of a corresponding avirulence (Avr) gene in the pathogen. A plant variety can be transformed with cloned resistance gene to engineer plants that are resistant to specific pathogen strains. See, for example Jones, et al., (1994) *Science* 266:789 (cloning of the tomato Cf-9 gene for resistance to *Cladosporium fulvum*); Martin, et al., (1993) *Science* 262:1432 (tomato Pto gene for resistance to *Pseudomonas syringae* pv. tomato encodes a protein kinase); Mindrinos, et al., (1994) *Cell* 78:1089 (*Arabidopsis* RSP2 gene for resistance to *Pseudomonas syringae*); McDowell and Woffenden, (2003) *Trends Biotechnol.* 21(4):178-83 and Toyoda, et al., (2002) *Transgenic Res.* 11(6):567-82. A plant resistant to a disease is one that is more resistant to a pathogen as compared to the wild type plant.

(B) A gene conferring resistance to fungal pathogens, such as oxalate oxidase or oxalate decarboxylase (Zhou, et al., (1998) *Pl. Physiol.* 117(1):33-41).

(C) A *Bacillus thuringiensis* protein, a derivative thereof or a synthetic polypeptide modeled thereon. See, for example, Geiser, et al., (1986) *Gene* 48:109, who disclose the cloning and nucleotide sequence of a Bt delta-endotoxin gene. Moreover, DNA molecules encoding delta-endotoxin genes can be purchased from American Type Culture Collection (Manassas, Va.), for example, under ATCC Accession Numbers. 40098, 67136, 31995 and 31998. Other examples of *Bacillus thuringiensis* transgenes being genetically engineered are given in the following patents and patent applications and hereby are incorporated by reference for this purpose: U.S. Pat. Nos. 5,188,960; 5,689,052; 5,880,275; WO 91/114778; WO 99/31248; WO 01/12731; WO 99/24581; WO 97/40162 and U.S. application Ser. Nos. 10/032,717; 10/414,637; and 10/606,320.

(D) An insect-specific hormone or pheromone such as an ecdysteroid and juvenile hormone, a variant thereof, a mimetic based thereon, or an antagonist or agonist thereof. See, for example, the disclosure by Hammock, et al., (1990) *Nature* 344:458, of baculovirus expression of cloned juvenile hormone esterase, an inactivator of juvenile hormone.

(E) An insect-specific peptide which, upon expression, disrupts the physiology of the affected pest. For example, see the disclosures of Regan, (1994) *J. Biol. Chem.* 269:9 (expression cloning yields DNA coding for insect diuretic hor-

mone receptor) and Pratt, et al., (1989) *Biochem. Biophys. Res. Comm.* 163:1243 (an allostatin is identified in *Diploptera puntata*); Chattopadhyay, et al., (2004) *Critical Reviews in Microbiology* 30(1):33-54 2004; Zjawiony, (2004) *J Nat Prod* 67(2):300-310; Carlini and Grossi-de-Sa, (2002) *Toxicon* 40(11):1515-1539; Ussuf, et al., (2001) *Curr Sci.* 80(7):847-853 and Vasconcelos and Oliveira, (2004) *Toxicon* 44(4):385-403. See also, U.S. Pat. No. 5,266,317 to Tomalski, et al., who disclose genes encoding insect-specific, paralytic neurotoxins.

(F) An enzyme responsible for a hyperaccumulation of a monoterpenes, a sesquiterpene, a steroid, hydroxamic acid, a phenylpropanoid derivative or another non-protein molecule with insecticidal activity.

(G) An enzyme involved in the modification, including the post-translational modification, of a biologically active molecule; for example, a glycolytic enzyme, a proteolytic enzyme, a lipolytic enzyme, a nuclease, a cyclase, a transaminase, an esterase, a hydrolase, a phosphatase, a kinase, a phosphorylase, a polymerase, an elastase, a chitinase and a glucanase, whether natural or synthetic. See PCT Application Number WO 93/02197 in the name of Scott, et al., which discloses the nucleotide sequence of a callase gene. DNA molecules which contain chitinase-encoding sequences can be obtained, for example, from the ATCC under Accession Numbers 39637 and 67152. See also, Kramer, et al., (1993) *Insect Biochem. Molec. Biol.* 23:691, who teach the nucleotide sequence of a cDNA encoding tobacco hookworm chitinase, and Kawalleck et al., (1993) *Plant Molec. Biol.* 21:673, who provide the nucleotide sequence of the parsley ubi4-2 polyubiquitin gene, U.S. patent application Ser. Nos. 10/389,432, 10/692,367 and U.S. Pat. No. 6,563,020.

(H) A molecule that stimulates signal transduction. For example, see the disclosure by Botella, et al., (1994) *Plant Molec. Biol.* 24:757, of nucleotide sequences for mung bean calmodulin cDNA clones, and Griess, et al., (1994) *Plant Physiol.* 104:1467, who provide the nucleotide sequence of a maize calmodulin cDNA clone.

(I) A hydrophobic moment peptide. See, PCT Application Number WO95/16776 and U.S. Pat. No. 5,580,852 (disclosure of peptide derivatives of Tachyplesin which inhibit fungal plant pathogens) and PCT Application Number WO95/18855 and U.S. Pat. No. 5,607,914 (teaches synthetic antimicrobial peptides that confer disease resistance), the respective contents of which are hereby incorporated by reference for this purpose.

(J) A membrane permease, a channel former or a channel blocker. For example, see the disclosure by Jaynes, et al., (1993) *Plant Sci.* 89:43, of heterologous expression of a cecropin-beta lytic peptide analog to render transgenic tobacco plants resistant to *Pseudomonas solanacearum*.

(K) A viral-invasive protein or a complex toxin derived therefrom. For example, the accumulation of viral coat proteins in transformed plant cells imparts resistance to viral infection and/or disease development effected by the virus from which the coat protein gene is derived, as well as by related viruses. See Beachy, et al., (1990) *Ann. Rev. Phytopathol.* 28:451. Coat protein-mediated resistance has been conferred upon transformed plants against alfalfa mosaic virus, cucumber mosaic virus, tobacco streak virus, potato virus X, potato virus Y, tobacco etch virus, tobacco rattle virus and tobacco mosaic virus. Id.

(L) An insect-specific antibody or an immunotoxin derived therefrom. Thus, an antibody targeted to a critical metabolic function in the insect gut would inactivate an affected enzyme, killing the insect. Cf. Taylor, et al., Abstract #497, SEVENTH INT'L SYMPOSIUM ON MOLECULAR

PLANT-MICROBE INTERACTIONS (Edinburgh, Scotland, 1994) (enzymatic inactivation in transgenic tobacco via production of single-chain antibody fragments).

(M) A virus-specific antibody. See, for example, Tavladoraki, et al., (1993) *Nature* 366:469, who show that transgenic plants expressing recombinant antibody genes are protected from virus attack.

(N) A developmental-arrestive protein produced in nature by a pathogen or a parasite. Thus, fungal endo alpha-1,4-D-polygalacturonases facilitate fungal colonization and plant nutrient release by solubilizing plant cell wall homo-alpha-1,4-D-galacturonase. See, Lamb, et al., (1992) *Bio/Technology* 10:1436. The cloning and characterization of a gene which encodes a bean endopolygalacturonase-inhibiting protein is described by Toubart, et al., (1992) *Plant J.* 2:367.

(O) A developmental-arrestive protein produced in nature by a plant. For example, Logemann, et al., (1992) *Bio/Technology* 10:305, have shown that transgenic plants expressing the barley ribosome-inactivating gene have an increased resistance to fungal disease.

(P) Genes involved in the Systemic Acquired Resistance (SAR) Response and/or the pathogenesis related genes. Briggs, (1995) *Current Biology* 5(2):128-131, Pieterse and Van Loon, (2004) *Curr. Opin. Plant Bio* 7(4):456-64 and Somssich, (2003) *Cell* 113(7):815-6.

(Q) Antifungal genes (Cornelissen and Melchers, (1993) *Pl. Physiol.* 101:709-712 and Parijs, et al., (1991) *Planta* 183:258-264 and Bushnell, et al., (1998) *Can. J. of Plant Path.* 20(2):137-149. Also see, U.S. patent application Ser. No. 09/950,933.

(R) Detoxification genes, such as for fumonisin, beauvericin, moniliformin and zearalenone and their structurally related derivatives. For example, see, U.S. Pat. No. 5,792,931.

(S) Cystatin and cysteine proteinase inhibitors. See, U.S. patent application Ser. No. 10/947,979.

(T) Defensin genes. See, WO03/000863 and U.S. patent application Ser. No. 10/178,213.

(U) Genes that confer resistance to *Phytophthora* Root Rot, such as the *Brassica* equivalents of the Rps 1, Rps 1-a, Rps 1-b, Rps 1-c, Rps 1-d, Rps 1-e, Rps 1-k, Rps 2, Rps 3-a, Rps 3-b, Rps 3-c, Rps 4, Rps 5, Rps 6, Rps 7 and other Rps genes. See, for example, Shoemaker, et al., (1995) *Phytophthora* Root Rot Resistance Gene Mapping in Soybean, Plant Genome IV Conference, San Diego, Calif.

2. Genes that Confer Resistance to a Herbicide, for Example:

(A) A herbicide that inhibits the growing point or meristem, such as an imidazalinone or a sulfonylurea. Exemplary genes in this category code for mutant ALS and AHAS enzyme as described, for example, by Lee, et al., (1988) *EMBO J.* 7:1241, and Miki, et al., (1990) *Theor. Appl. Genet.* 80:449, respectively. See also, U.S. Pat. Nos. 5,605,011; 5,013,659; 5,141,870; 5,767,361; 5,731,180; 5,304,732; 4,761,373; 5,331,107; 5,928,937 and 5,378,824; and international publication WO 96/33270, which are incorporated herein by reference for this purpose.

(B) Glyphosate (resistance imparted by mutant 5-enolpyruvyl-3-phosphokimate synthase (EPSP) and aroA genes, respectively) and other phosphono compounds such as glufosinate (phosphinothricin acetyl transferase, PAT) and *Streptomyces hygroscopicus* phosphinothricin-acetyl transferase, bar, genes), and pyridinoyl or phenoxy propionic acids and cyclohexones (ACCase inhibitor-encoding genes). See, for example, U.S. Pat. No. 4,940,835 to Shah, et al., which discloses the nucleotide sequence of a form of EPSP which can confer glyphosate resistance. See also, U.S. Pat. No. 7,405,074, and related applications, which disclose com-

positions and means for providing glyphosate resistance. U.S. Pat. No. 5,627,061 to Barry, et al., also describes genes encoding EPSPS enzymes. See also, U.S. Pat. Nos. 6,566,587; 6,338,961; 6,248,876 B1; 6,040,497; 5,804,425; 5,633,435; 5,145,783; 4,971,908; 5,312,910; 5,188,642; 4,940,835; 5,866,775; 6,225,114 B1; 6,130,366; 5,310,667; 4,535,060; 4,769,061; 5,633,448; 5,510,471; Re. 36,449; RE 37,287 E; and 5,491,288; and international publications EP1173580; WO 01/66704; EP1173581 and EP1173582, which are incorporated herein by reference for this purpose. A DNA molecule encoding a mutant aroA gene can be obtained under ATCC Accession Number 39256, and the nucleotide sequence of the mutant gene is disclosed in U.S. Pat. No. 4,769,061 to Comai. European Patent Application Number 0 333 033 to Kumada, et al., and U.S. Pat. No. 4,975,374 to Goodman, et al., disclose nucleotide sequences of glutamine synthetase genes which confer resistance to herbicides such as L-phosphinothricin. The nucleotide sequence of a phosphinothricin-acetyl-transferase gene is provided in European Application Number 0 242 246 to Leemans, et al., De Greef, et al., (1989) *Bio/Technology* 7:61, describe the production of transgenic plants that express chimeric bar genes coding for phosphinothricin acetyl transferase activity. See also, U.S. Pat. Nos. 5,969,213; 5,489,520; 5,550,318; 5,874,265; 5,919,675; 5,561,236; 5,648,477; 5,646,024; 6,177,616 B1 and 5,879,903, which are incorporated herein by reference for this purpose. Exemplary of genes conferring resistance to phenoxy propionic acids and cyclohexones, such as sethoxydim and haloxyfop, are the Acc1-S1, Acc1-S2 and Acc1-S3 genes described by Marshall, et al., (1992) *Theor. Appl. Genet.* 83:435. See also, U.S. Pat. Nos. 5,188,642; 5,352,605; 5,530,196; 5,633,435; 5,717,084; 5,728,925; 5,804,425 and Canadian Patent Number 1,313,830, which are incorporated herein by reference for this purpose.

(C) A herbicide that inhibits photosynthesis, such as a triazine (psbA and gs+ genes) and a benzonitrile (nitrilase gene). Przibilla, et al., (1991) *Plant Cell* 3:169, describe the transformation of *Chlamydomonas* with plasmids encoding mutant psbA genes. Nucleotide sequences for nitrilase genes are disclosed in U.S. Pat. No. 4,810,648 to Stalker, and DNA molecules containing these genes are available under ATCC Accession Numbers 53435, 67441 and 67442. Cloning and expression of DNA coding for a glutathione S-transferase is described by Hayes, et al., (1992) *Biochem. J.* 285:173.

(D) Acetohydroxy acid synthase, which has been found to make plants that express this enzyme resistant to multiple types of herbicides, has been introduced into a variety of plants (see, e.g., Hattori, et al., (1995) *Mol Gen Genet* 246: 419). Other genes that confer tolerance to herbicides include: a gene encoding a chimeric protein of rat cytochrome P450A1 and yeast NADPH-cytochrome P450 oxidoreductase (Shiota, et al., (1994) *Plant Physiol* 106:17), genes for glutathione reductase and superoxide dismutase (Aono, et al., (1995) *Plant Cell Physiol* 36:1687, and genes for various phosphotransferases (Datta, et al., (1992) *Plant Mol Biol* 20:619).

(E) Protoporphyrinogen oxidase (protox) is necessary for the production of chlorophyll, which is necessary for all plant survival. The protox enzyme serves as the target for a variety of herbicidal compounds. These herbicides also inhibit growth of all the different species of plants present, causing their total destruction. The development of plants containing altered protox activity which are resistant to these herbicides are described in U.S. Pat. Nos. 6,288,306 B1; 6,282,837 B1; and 5,767,373; and international publication WO 01/12825, which are incorporated herein by reference for this purpose.

### 3. Transgenes that Confer or Contribute to an Altered Grain Characteristic, Such as:

#### (A) Altered fatty acids, for example, by

- (1) Down-regulation of stearoyl-ACP desaturase to increase stearic acid content of the plant. See, Knultzon, et al., (1992) *Proc. Natl. Acad. Sci. USA* 89:2624 and WO99/64579 (Genes for Desaturases to Alter Lipid Profiles in Corn),
- (2) Elevating oleic acid via FAD-2 gene modification and/or decreasing linolenic acid via FAD-3 gene modification (see, U.S. Pat. Nos. 6,063,947; 6,323,392; 6,372,965 and WO 93/11245),
- (3) Altering conjugated linolenic or linoleic acid content, such as in WO 01/12800,
- (4) Altering LEC1, AGP, Dek1, Superal1, milps, various Ipa genes such as Ipa1, Ipa3, hpt or hgg. For example, see WO 02/42424, WO 98/22604, WO 03/011015, U.S. Pat. Nos. 6,423,886, 6,197,561, 6,825,397, US Patent Application Publication Numbers 2003/0079247, 2003/0204870, WO02/057439, WO03/011015 and Rivera-Madrid, et al., (1995) *Proc. Natl. Acad. Sci.* 92:5620-5624.

#### (B) Altered phosphorus content, for example, by the

- (1) Introduction of a phytase-encoding gene would enhance breakdown of phytate, adding more free phosphate to the transformed plant. For example, see, Van Hartingsveldt, et al., (1993) *Gene* 127:87, for a disclosure of the nucleotide sequence of an *Aspergillus niger* phytase gene.
- (2) Up-regulation of a gene that reduces phytate content. In maize, this, for example, could be accomplished, by cloning and then re-introducing DNA associated with one or more of the alleles, such as the LPA alleles, identified in maize mutants characterized by low levels of phytic acid, such as in Raboy, et al., (1990) *Maydica* 35:383 and/or by altering inositol kinase activity as in WO 02/059324, US Patent Application Publication Number 2003/0009011, WO 03/027243, US Patent Application Publication Number 2003/0079247, WO 99/05298, U.S. Pat. Nos. 6,197,561, 6,291,224, 6,391,348, WO2002/059324, US Patent Application Publication Number 2003/0079247, WO98/45448, WO99/55882, WO01/04147.

(C) Altered carbohydrates effected, for example, by altering a gene for an enzyme that affects the branching pattern of starch, a gene altering thioredoxin. (See, U.S. Pat. No. 6,531,648). See, Shiroza, et al., (1988) *J. Bacteriol* 170:810 (nucleotide sequence of *Streptococcus mutans* fructosyltransferase gene), Steinmetz, et al., (1985) *Mol. Gen. Genet.* 200:220 (nucleotide sequence of *Bacillus subtilis* levansucrase gene), Pen, et al., (1992) *Bio/Technology* 10:292 (production of transgenic plants that express *Bacillus licheniformis* alpha-amylase), Elliot, et al., (1993) *Plant Molec Biol* 21:515 (nucleotide sequences of tomato invertase genes), Søgaard, et al., (1993) *J. Biol. Chem.* 268:22480 (site-directed mutagenesis of barley alpha-amylase gene) and Fisher, et al., (1993) *Plant Physiol* 102:1045 (maize endosperm starch branching enzyme II), WO 99/10498 (improved digestibility and/or starch extraction through modification of UDP-D-xylose 4-epimerase, Fragile 1 and 2, Ref1, HCHL, C4H), U.S. Pat. No. 6,232,529 (method of producing high oil seed by modification of starch levels (AGP)). The fatty acid modification genes mentioned above may also be used to affect starch content and/or composition through the interrelationship of the starch and oil pathways.

(D) Altered antioxidant content or composition, such as alteration of tocopherol or tocotrienols. For example, see,

U.S. Pat. No. 6,787,683, US Patent Application Publication Number 2004/0034886 and WO 00/68393 involving the manipulation of antioxidant levels through alteration of a phytol prenyl transferase (ppt), WO 03/082899 through alteration of a homogentisate geranyl geranyl transferase (hgg).

(E) Altered essential seed amino acids. For example, see, U.S. Pat. No. 6,127,600 (method of increasing accumulation of essential amino acids in seeds), U.S. Pat. No. 6,080,913 (binary methods of increasing accumulation of essential amino acids in seeds), U.S. Pat. No. 5,990,389 (high lysine), WO99/40209 (alteration of amino acid compositions in seeds), WO99/29882 (methods for altering amino acid content of proteins), U.S. Pat. No. 5,850,016 (alteration of amino acid compositions in seeds), WO98/20133 (proteins with enhanced levels of essential amino acids), U.S. Pat. No. 5,885,802 (high methionine), U.S. Pat. No. 5,885,801 (high threonine), U.S. Pat. No. 6,664,445 (plant amino acid biosynthetic enzymes), U.S. Pat. No. 6,459,019 (increased lysine and threonine), U.S. Pat. No. 6,441,274 (plant tryptophan synthase beta subunit), U.S. Pat. No. 6,346,403 (methionine metabolic enzymes), U.S. Pat. No. 5,939,599 (high sulfur), U.S. Pat. No. 5,912,414 (increased methionine), WO98/56935 (plant amino acid biosynthetic enzymes), WO98/45458 (engineered seed protein having higher percentage of essential amino acids), WO98/42831 (increased lysine), U.S. Pat. No. 5,633,436 (increasing sulfur amino acid content), U.S. Pat. No. 5,559,223 (synthetic storage proteins with defined structure containing programmable levels of essential amino acids for improvement of the nutritional value of plants), WO96/01905 (increased threonine), WO95/15392 (increased lysine), US Patent Application Publication Number 2003/0163838, US Patent Application Publication Number 2003/0150014, US Patent Application Publication Number 2004/0068767, U.S. Pat. No. 6,803,498, WO01/79516, and WO00/09706 (Ces A: cellulose synthase), U.S. Pat. No. 6,194,638 (hemicellulose), U.S. Pat. No. 6,399,859 and US Patent Application Publication Number 2004/0025203 (UDP-GdH), U.S. Pat. No. 6,194,638 (RGP).

### 4. Genes that Control Pollination, Hybrid Seed Production or Male-Sterility:

There are several methods of conferring genetic male sterility available, such as multiple mutant genes at separate locations within the genome that confer male sterility, as disclosed in U.S. Pat. Nos. 4,654,465 and 4,727,219 to Brar, et al., and chromosomal translocations as described by Patterson in U.S. Pat. Nos. 3,861,709 and 3,710,511. In addition to these methods, Albertsen, et al., U.S. Pat. No. 5,432,068, describe a system of nuclear male sterility which includes: identifying a gene which is critical to male fertility; silencing this native gene which is critical to male fertility; removing the native promoter from the essential male fertility gene and replacing it with an inducible promoter; inserting this genetically engineered gene back into the plant; and thus creating a plant that is male sterile because the inducible promoter is not "on" resulting in the male fertility gene not being transcribed. Fertility is restored by inducing, or turning "on", the promoter, which in turn allows the gene that confers male fertility to be transcribed.

(A) Introduction of a deacetylase gene under the control of a tapetum-specific promoter and with the application of the chemical N-Ac-PPT (WO 01/29237).

(B) Introduction of various stamen-specific promoters (WO 92/13956, WO 92/13957).

(C) Introduction of the barnase and the barstar gene (Paul, et al., (1992) *Plant Mol. Biol.* 19:611-622).

For additional examples of nuclear male and female sterility systems and genes, see also, U.S. Pat. Nos. 5,859,341;

6,297,426; 5,478,369; 5,824,524; 5,850,014 and 6,265,640; all of which are hereby incorporated by reference.

Also see, U.S. Pat. No. 5,426,041 (invention relating to a method for the preparation of a seed of a plant comprising crossing a male sterile plant and a second plant which is male fertile), U.S. Pat. No. 6,013,859 (molecular methods of hybrid seed production) and U.S. Pat. No. 6,037,523 (use of male tissue-preferred regulatory region in mediating fertility), all of which are hereby incorporated by reference for this purpose.

#### 5. Genes that Create a Site for Site Specific DNA Integration.

This includes the introduction of FRT sites that may be used in the FLP/FRT system and/or Lox sites that may be used in the Cre/Loxp system. For example, see, Lyznik, et al., (2003) "Site-Specific Recombination for Genetic Engineering in Plants", *Plant Cell Rep* 21:925-932 and WO 99/25821, which are hereby incorporated by reference. Other systems that may be used include the Gin recombinase of phage Mu (Maeser, et al., 1991), the Pin recombinase of *E. coli* (Enomoto, et al., 1983), and the R/RS system of the pSR1 plasmid (Araki, et al., 1992).

6. Genes that affect abiotic stress resistance (including but not limited to flowering, ear and seed development, enhancement of nitrogen utilization efficiency, altered nitrogen responsiveness, drought resistance or tolerance, cold resistance or tolerance, and salt resistance or tolerance) and increased yield under stress.

For example, see, WO 00/73475 where water use efficiency is altered through alteration of malate; U.S. Pat. Nos. 5,892,009, 5,965,705, 5,929,305, 5,891,859, 6,417,428, 6,664,446, 6,706,866, 6,717,034, 6,801,104, WO2000060089, WO2001026459, WO2001035725, WO2001034726, WO2001035727, WO2001036444, WO2001036597, WO2001036598, WO2002015675, WO2002017430, WO2002077185, WO2002079403, WO2003013227, WO2003013228, WO2003014327, WO2004031349, WO2004076638, WO9809521 and WO9938977 describing genes, including CBF genes and transcription factors effective in mitigating the negative effects of freezing, high salinity, and drought on plants, as well as conferring other positive effects on plant phenotype; US Patent Application Publication Number 2004/0148654 and WO01/36596 where abscisic acid is altered in plants resulting in improved plant phenotype such as increased yield and/or increased tolerance to abiotic stress; WO2000/006341, WO04/090143, U.S. patent application Ser. Nos. 10/817,483 and 09/545,334 where cytokinin expression is modified resulting in plants with increased stress tolerance, such as drought tolerance, and/or increased yield. Also see WO0202776, WO03052063, JP2002281975, U.S. Pat. No. 6,084,153, WO0164898, U.S. Pat. No. 6,177,275 and U.S. Pat. No. 6,107,547 (enhancement of nitrogen utilization and altered nitrogen responsiveness). For ethylene alteration, see, US Patent Application Publication Numbers 2004/0128719, 2003/0166197 and WO200032761. For plant transcription factors or transcriptional regulators of abiotic stress, see e.g., US Patent Application Publication Number 2004/0098764 or US Patent Application Publication Number 2004/0078852.

Other genes and transcription factors that affect plant growth and agronomic traits such as yield, flowering, plant growth and/or plant structure, can be introduced or introgressed into plants, see, e.g., WO97/49811 (LHY), WO98/56918 (ESD4), WO97/10339 and U.S. Pat. No. 6,573,430 (TFL), U.S. Pat. No. 6,713,663 (FT), WO96/14414 (CON), WO96/38560, WO01/21822 (VRN1), WO00/44918 (VRN2), WO99/49064 (GI), WO00/46358 (FRI), WO97/29123, U.S. Pat. Nos. 6,794,560, 6,307,126 (GAI), WO99/

09174 (D8 and Rht), and WO2004076638 and WO2004031349 (transcription factors).

#### INDUSTRIAL APPLICABILITY

The seed of the 45S52 variety, the plant produced from such seed, various parts of the 45S52 hybrid canola plant or its progeny, a canola plant produced from the crossing of the 45S52 variety, and the resulting seed, can be utilized in the production of an edible vegetable oil or other food products in accordance with known techniques. The remaining solid meal component derived from seeds can be used as a nutritious livestock feed.

#### DEPOSITS

Applicant has made or will make a deposit of at least 2500 seeds of canola variety 45S52 with the American Type Culture Collection (ATCC), 10801 University Boulevard, Manassas, Va. 20110 USA, with ATCC Deposit No. PTA-122482. The seeds deposited with the ATCC on Aug. 20, 2015 for PTA-122482 were taken from the seed stock maintained by Pioneer Hi-Bred International, Inc., 7250 NW 62<sup>nd</sup> Avenue, Johnston, Iowa 50131-1000 since prior to the filing date of this application. Access to these deposits will be available during the pendency of the application to the Commissioner of Patents and Trademarks and persons determined by the Commissioner to be entitled thereto upon request. Upon allowance of any claims in the application, the Applicant will make available to the public, pursuant to 37 C.F.R. §1.808, sample(s) of the deposit of at least 2500 seeds of parental canola varieties NS5902FR and NS6418MC with the American Type Culture Collection (ATCC), 10801 University Boulevard, Manassas, Va. 20110-2209. The deposits of seed of parental canola varieties NS5902FR and NS6418MC will be maintained in the ATCC depository, which is a public depository, for a period of 30 years, or 5 years after the most recent request, or for the enforceable life of the patent, whichever is longer, and will be replaced if it becomes nonviable during that period. Additionally, Applicant has or will satisfy all the requirements of 37 C.F.R. §§1.801-1.809, including providing an indication of the viability of the sample upon deposit. Applicant has no authority to waive any restrictions imposed by law on the transfer of biological material or its transportation in commerce. Applicant does not waive any infringement of their rights granted under this patent or rights applicable to canola hybrid 45S52 or of parental canola varieties NS5902FR and NS6418MC under the Plant Variety Protection Act (7 USC 2321 et seq.). The foregoing invention has been described in detail by way of illustration and example for purposes of exemplification. However, it will be apparent that changes and modifications such as single gene modifications and mutations, somaclonal variants, variant individuals selected from populations of the plants of the instant variety, and the like, are considered to be within the scope of the present invention. All references disclosed herein whether to journal, patents, published applications and the like are hereby incorporated in their entirety by reference.

#### Example 1

##### Herbicide Resistance

Appropriate field tests (in compliance with both CFIA-variety registration office and the herbicide provider) in two growing seasons have shown that 45S52 tolerates the recom-

## US 9,179,632 B1

29

mended rate (1.5 L/ha) of Roundup® (glyphosate) herbicide without showing plant injury or any significant effect on

30

yield, agronomic, or quality traits. This hybrid exhibits less than 1500/10,000 (<15%) glyphosate-susceptible plants.

## Example 2

## Black Leg Tolerance

Blackleg tolerance was rated on a scale of 0 to 5: a plant with zero rating is completely immune to disease while a plant with "5" rating is dead due to blackleg infection. At each site, four replicated experiment were planted and twenty five plants per plot were rated for blackleg tolerance.

For each test entry, 25 plants were assessed from each of a minimum of four replicates of a naturally infected or artificially inoculated field test. Plants in blackleg trials were rated at the 5.2 stage on the Harper and Berkenkamp scale and that evaluation of disease reaction was based on the extent of the infection throughout the stem. This was evaluated by cutting open the stem at the site of the canker.

Tests were rated using a 0-5 scale, as follows:

0—no diseased tissue visible in the cross-section

1—Diseased tissue occupies up to 25% of cross-section

2—Diseased tissue occupies 26-50% of cross-section

3—Diseased tissue occupies 51-75% of cross-section

4—Diseased tissue occupies more than 75% of cross-section with little or no constriction of affected tissues

5—Diseased tissue occupies 100% of cross-section with significant constriction of affected tissues; tissue dry and brittle; plant dead.

Canola variety "Westar" was included as an entry/control in each blackleg trial. Tests are considered valid when the mean rating for Westar is greater than or equal to 2.6 and less than or equal to 4.5. (In years when there is poor disease development in Western Canada the WCC/RRC may accept the use of data from trials with a rating for Westar exceeding 2.0.)

The ratings are converted to a percentage severity index for each line, and the following scale is used to describe the level of resistance:

Classification	Rating (% of Westar)
R (Resistant)	<30
MR (Moderately Resistant)	30-49
MS (Moderately Susceptible)	50-69
S (Susceptible)	70-100

## Example 3

## Summary of Agronomic Performance of 45S52 in Two Years of Testing

Two years (2008 and 2009) of trials were conducted at a total of 39 locations. WCC/RRC guidelines were followed for conducting trials. Each trial had four replicates and had a plot size of 1.5 m×6 m. Yield and agronomic traits were recorded and seed samples were collected from two of the four replicates at selected sites and were analyzed for quality traits such as oil and protein percent at 8.5% moisture, total whole seed glucosinolates at 8.5%, chlorophyll, total saturated fatty acid, 1000 seed weight etc. WCC/RRC guidelines were followed for analyzing quality parameters.

Summary of *Sclerotinia* Resistance in 45S52

Two sets of replicated field experiments were carried out during 2008 and 2009 seasons. Prior to physiological maturity, observations on disease severity (Table 5) and frequency (incidence) of infected plants were recorded. These two observations were combined into one *Sclerotinia sclerotiorum* Field Severity number using the formula of Bradley et al. (2004), where  $SSFS = ((\% \text{ disease incidence} \times \text{disease severity})/5)$ .

TABLE 5

Disease severity rating utilized in collecting field data on individual plants			
Disease severity rating	Symptoms		
	Main Stem	Primary Branches (Off main stem)	Secondary Branches (Off primary)
5	Prematurely ripened or dying plant		
4	Girdled stem, plant not ripened*	More than two dead or dying branches	

34

TABLE 5-continued

Disease severity rating utilized in collecting field data on individual plants			
Disease severity rating	Symptoms		
	Main Stem	Primary Branches (Off main stem)	Secondary Branches (Off primary)
3	Incomplete girdling	Two dead or dying branches	
2	Large non-girdling lesion	One dead or dying branch	More than two affected branches
1	Small non-girdling lesion	Girdling or lesion	One to two affected branches
0	No symptoms		
15	*Individual and/or combined symptoms quantified to produce disease severity rating		

According to the SSFS calculation, a canola field with all plants infected (100% incidence) and a severity score of 1 will have SSFS=20. That is the same outcome as in another field where 20% of the plants are infected (20% incidence), and each with a rating of 5 (SSFS=20). Yield losses at field level can be estimated to be approximately half of the SSFS score. At the moment, all commercial canola varieties sold in Canada are susceptible to *Sclerotinia* with the exception of 45S51. The SSFS value can be a predictor of yield loss at field scale. Also, the SSFS allows straight comparison from one field to another as it is ultimately translated as yield loss. With different degree of SSFS, it is possible to classify the cultivar into various groups such as highly susceptible—HS, susceptible—S, Moderately susceptible—MS, Moderately Resistant—MR, Resistant—R and Highly Resistant—HR. Similar grouping has been done for other disease like blackleg as presented in Table 6.

TABLE 6

Possible classification of canola varieties for tolerance most severe possible <i>Sclerotinia</i> disease pressure				
Field performance Category	Disease Incidence	Disease Severity*	SSFS Field severity	Yield loss Estimate
Highly susceptible	80-100	5	80-100	40-50
Susceptible	70-79	5	70-79	35-39.5
Moderately susceptible	50-69	5	50-69	25-34.5
Moderately resistant	30-49	5	30-49	15-24.5
Resistant	10-29	5	10-29	5-14.5
Highly resistant	0-9	5	0-9	0-4.5

Year 1: This experiment was conducted in 2008 at 12 locations where 45S52 was planted using randomized complete block design with other entries and two commercial checks 45H26 and 45S51. Five locations had acceptable disease pressure (>10% SSFS on susceptible check). Those locations were Crystal City, Carman, Winkler and Rosebank in Southern Manitoba and Orangeville (5ST) in Ontario. There were five replications in each site. Prior to physiological maturity, disease incidence and severity were recorded on each plot in each replicate (50 plants per plot). These averages were then transformed into SSFS. The SSFS values from this experiment for 45S52, 45H26 and 45S51 are presented in Table 7.

During the 2008 trial, *Sclerotinia* disease incidence and severity were satisfactory. Carman and Orangeville were under irrigation (5CR, 5ST) while other locations were not irrigated. Irrigation helps with conditions for disease development but can affect standability of varieties and impact the SSFS scores. 45S52 performed better than 45S51 and it almost scored R relative to 45H26. 45S52 is improved for standability and that can be a factor under irrigation vs. 45S51

35

at Carman for instance. If Carman was excluded, 45S51 performed very well showing the level of field tolerance to *Sclerotinia* relative to 45H26. Overall, 45S52 showed very consistent high level of field tolerance to *Sclerotinia* in 2008.

Year 2: This experiment was conducted in 2009 where 45S52 and two commercial hybrids with similar days to flowering & maturity were tested. Susceptible check 45H26 was tested with and without fungicide application (Lance® or Proline®). Six replications were planted at each of 14 locations. Prior to physiological maturity, disease incidence and severity were recorded on each plot in each replicate. These averages were then transformed into SSFS. The SSFS values from this experiment for 45S52, 45H26, 45H26 (fungicide treated) and 45S51 are presented in Table 4.

Sufficient disease pressure (>10% SSFS on susceptible check) was attained at Winkler and Portage la Prairie in Southern Manitoba, Rockwood and Fergus in Ontario and Charlottetown in PEI. Winkler location was subject to excessive irrigation-caused lodging where disease spread from plan to plant via contact infection affecting performance of varieties and fungicide.

Location Winkler was under irrigation that affected standability and performance of 45S51 as well as fungicide treatment. On the other hand, lower pressure location like 5PEI does not differentiate varieties as well as higher pressure locations without irrigation while fungicide treatments tend to be very efficacious in such marginal environments. The level of field tolerance of 45S52 to *Sclerotinia* was on average similar to fungicide-protected 45H26. 45S51 performed as expected with exceptions of low pressure and high lodging pressure at Winkler.

Looking at two year summary in Table 9, we can see that 45S52 is significantly improved for its field tolerance to *Sclerotinia*, exhibiting stability across years and various environments disease pressure-wise. A part of that improvement is improved standability which was obvious under irrigation in Carman (2008) and Winkler (2009).

45S52 was tested in large scale strip trials along 45H28 and 45S51 commercial checks. Visual observations from five locations harboring sufficient levels of disease (10% SSFS on 45H28) in Manitoba (2), North Dakota (1), Ontario (1) and Quebec (1) were consistent with small plot data and showed significant reduction of disease development on 45S52.

TABLE 7

<i>Sclerotinia sclerotiorum</i> Field Severity (SSFS) on 45S52, 45H26 and 45S51 across five locations in 2008								
Variety	5WK	5ST	3CC	5CR	5RB	SSFS mean	% of susceptible	Category
45S52	3.4	7.1	11.2	6.3	2.6	6.1	30	MR
45S51	5.9	8.6	11.6	14.5	5.9	9.3	45	MR

\*Results affected by excessive irrigation causing lodging and direct/contact infection at Winkler (MB)

The foregoing invention has been described in detail by way of illustration and example for purposes of clarity and understanding. As is readily apparent to one skilled in the art, the foregoing are only some of the methods and compositions that illustrate the embodiments of the foregoing invention. It will be apparent to those of ordinary skill in the art that variations, changes, modifications and alterations may be applied to the compositions and/or methods described herein without departing from the true spirit, concept and scope of the invention.

What is claimed is:

1. A plant, plant part, seed, or cell of canola variety 45S52, wherein representative seed of canola variety 45S52 has been deposited under ATCC Accession Number PTA-122482.

2. The seed of claim 1, further comprising a transgenic event.

3. The seed of claim 2, wherein the transgenic event confers a trait selected from the group consisting of male sterility, site-specific recombination, abiotic stress tolerance, altered phosphorus, altered antioxidants, altered fatty acids, altered essential amino acids, altered carbohydrates, herbicide resistance, insect resistance and disease resistance.

4. A converted seed of canola variety 45S52 further comprising a locus conversion, wherein the converted seed produces a plant which has otherwise essentially the same phenotypic characteristics of canola variety 45S52 listed in Table 1 when grown under the same environmental conditions, and wherein representative seed of canola variety 45S52 has been deposited under ATCC Accession Number PTA-122482.

5. The seed of claim 4, wherein the locus conversion confers a trait selected from the group consisting of male sterility, site-specific recombination, abiotic stress tolerance, altered phosphorus, altered antioxidants, altered fatty acids, altered essential amino acids, altered carbohydrates, herbicide resistance, insect resistance and disease resistance.

6. A method for producing a second canola plant comprising applying plant breeding techniques to a first canola plant, or parts thereof, wherein said first canola plant is the canola plant of claim 1, and wherein application of said techniques results in the production of said second canola plant.

37

7. The method of claim 6, further defined as producing an inbred canola plant derived from canola variety 45S52, the method comprising the steps of:

- (a) crossing said first canola plant with itself or another canola plant to produce seed of a subsequent generation;
- (b) harvesting and planting the seed of the subsequent generation to produce at least one plant of the subsequent generation; and
- (c) repeating steps (a) and (b) for an additional 2-10 generations to produce an inbred canola plant derived from canola variety 45S52.

8. The method of claim 6, further defined as producing an inbred canola plant derived from canola variety 45S52, the method comprising the steps of:

- (a) crossing said first canola plant with an inducer variety to produce haploid seed; and
- (b) doubling the haploid seed to produce an inbred canola plant derived from canola variety 45S52.

9. The plant or plant part of claim 1, further comprising a transgenic event.

10. The plant of claim 9, wherein the transgenic event confers a trait selected from the group consisting of selected from the group consisting of male sterility, site-specific recombination, abiotic stress tolerance, altered phosphorus, altered antioxidants, altered fatty acids, altered essential amino acids, altered carbohydrates, herbicide resistance, insect resistance and disease resistance.

11. A method for producing a second canola plant comprising applying plant breeding techniques to a first canola plant, or parts thereof, wherein said first canola plant is the canola plant of claim 9, and wherein application of said techniques results in the production of said second canola plant.

12. The method of claim 11, further defined as producing an inbred canola plant derived from canola variety 45S52, the method comprising the steps of:

- (a) crossing said first canola plant with itself or another canola plant to produce seed of a subsequent generation;
- (b) harvesting and planting the seed of the subsequent generation to produce at least one plant of the subsequent generation; and
- (c) repeating steps (a) and (b) for an additional 2-10 generations to produce an inbred canola plant derived from canola variety 45S52.

38

13. The method of claim 11, further defined as producing an inbred canola plant derived from canola variety 45S52, the method comprising the steps of:

- (a) crossing said first canola plant with an inducer variety to produce haploid seed; and
- (b) doubling the haploid seed to produce an inbred canola plant derived from canola variety 45S52.

14. A converted plant or plant part wherein said plant or plant part is produced by growing the seed of claim 4, wherein the converted plant or plant part has otherwise essentially the same phenotypic characteristics of canola variety 45S52 listed in Table 1 when grown under the same environmental conditions.

15. The plant or plant part of claim 14, wherein the locus conversion confers a trait selected from the group consisting of male sterility, site-specific recombination, abiotic stress tolerance, altered phosphorus, altered antioxidants, altered fatty acids, altered essential amino acids, altered carbohydrates, herbicide resistance, insect resistance and disease resistance.

16. A method for producing a second canola plant comprising applying plant breeding techniques to a first canola plant, or parts thereof, wherein said first canola plant is the canola plant of claim 14, and wherein application of said techniques results in the production of said second canola plant.

17. The method of claim 16, further defined as producing an inbred canola plant derived from canola variety 45S52, the method comprising the steps of:

- (a) crossing said first canola plant with itself or another canola plant to produce seed of a subsequent generation;
- (b) harvesting and planting the seed of the subsequent generation to produce at least one plant of the subsequent generation; and
- (c) repeating steps (a) and (b) for an additional 2-10 generations to produce an inbred canola plant derived from canola variety 45S52.

18. The method of claim 16, further defined as producing an inbred canola plant derived from canola variety 45S52, the method comprising the steps of:

- (a) crossing said first canola plant with an inducer variety to produce haploid seed; and
- (b) doubling the haploid seed to produce an inbred canola plant derived from canola variety 45S52.
